

# Recursion and Advanced Data Structures: Takeaways

by Dataquest Labs, Inc. - All rights reserved © 2021

## Syntax

- Using recursion to return the  $n^{th}$  Fibonacci number:

```
def fib(n):  
    if n == 0 or n == 1:  
        return 1  
    return fib(n - 1) + fib(n - 2)
```

- Getting the length of the linked list using iteration:

```
def length_iterative(ls):  
    count = 0  
    while not ls.is_empty():  
        count = count + 1  
        ls = ls.tail()  
    return count
```

- Using recursion to find the length of a linked list:

```
def length_recursive(ls):  
    if ls.is_empty():  
        return 0  
    return 1 + length_recursive(ls.tail())
```

## Concepts

- Recursion is the method of repeating code without using loops. An example of recursion would be the factorial function in mathematics.
  - We denote a factorial using the `!` sign. For example `n!` denotes multiplying `n` by all the positive integers less than `n`. However, `0!` is defined as 1.
    - For example: `5! = 5 * 4 * 3 * 2 * 1`.
- A linked list is made up of many nodes. In a singly linked list, each node contains its data as well as the next node.
- A linked list is a type a recursive data structure since each node contains the data and then points to another linked list.
- An advantage of using linked lists is that you need to modify very few nodes when inserting or deleting because the update only requires a constant amount of changes.
